

Webs and skew Howe duality

What is a pivotal category?

\Rightarrow a tensor category with 'nice' duals

Duality means a functor $*$: $\mathcal{C} \rightarrow \mathcal{C}^{\text{op op}}$
with $** = \text{id}$

along with structure maps

$$\text{'pairing'}: V^* \otimes V \rightarrow \mathbb{1}$$

$$\text{and 'copairing'}: \mathbb{1} \rightarrow V \otimes V^*$$

satisfying the axioms you'd expect (eg. from linear algebra)

Examples

- $\text{Rep } G$, for G a finite group
- $\text{Rep } U_q \mathfrak{g}$ representations of a quantum group
- A - A bimodules generated by ${}_A B_A$, where $A \subset B$ is a finite index subfactor
- Deligne's interpolated symmetric groups $\text{Rep } S_t$.

Pivotal categories have a diagrammatic calculus

algebra	pictures
composition	vertical stacking
\otimes -product	horizontal juxtaposition
*	π -rotation
$P_V: V^* \otimes V \rightarrow \mathbb{1}$	
$C_V: \mathbb{1} \rightarrow V \otimes V^*$	

Example

$$(h \otimes f \otimes \text{id}_{A^*}) \circ (g \otimes C_A) \iff$$

Fundamental theorem of pivotal categories:

if two diagrams are planar isotopic, ~~the~~
the morphisms they represent are equal.

Which diagrams do we need to describe a particular pivotal category?

Kuperberg's program:

Give generators and relations (ie a presentation as a pivotal category) for every pivotal category you know.

Examples

- $\text{Rep}^{\text{uni}} U_q \underline{\underline{\mathfrak{sl}}}_2 = \text{TL}(q+q^{-1})$

↗ a pivotal category with no generators, just unlabelled strings, and one relation:

$$0 = q + q^{-1}.$$

(actually, you need to idempotent complete TL)

- $\text{Rep } U_q \underline{\underline{\mathfrak{sl}}}_3 \xrightarrow{\text{Kuperberg}} \left\langle \begin{array}{c} \text{fork}, \text{triangle} \end{array} \mid \begin{array}{c} Q = [3] \quad \uparrow Q = -[2] \quad \uparrow \\ \square = \text{ } \quad \left(+ \text{ } \right) \end{array} \right\rangle$

- this is more or less how we constructed the extended Haagerup subfactor.

Today, let's do $U_q \underline{\underline{\mathfrak{sl}}}_n$.

(Some history: Kim conjectured a presentation for $n=4$ in 2004,
I conjectured a presentation for all n in 2007,

arXiv:1210.6437 with Sabin Cautis and
Joel Kamnitzer

completes the story.)

The free SL_n spider just consists of planar diagram locally modelled on the following four vertices:

Example

is a morphism

$$2^+ 4^+ 1^+ \rightarrow 1^- 1^- 1^+$$

There's a functor (unique up to some normalizations)
to RepSL_n

$$\mapsto (\wedge^a \oplus \wedge^b \rightarrow \wedge^{a+b})$$

$$\mapsto (\wedge^{a+b} \rightarrow \wedge^a \otimes \wedge^b)$$

$$\mapsto \left(\wedge^a \rightarrow (\wedge^{n-a})^* \right)$$

$$\mapsto \left((\wedge^a)^* \rightarrow \wedge^{n-a} \right)$$

~~Edges~~ • Edges labelled 0 and n are a notational convenience:
delete 0 edges, replace $\begin{matrix} a \\ \downarrow \\ \text{---} \\ \uparrow \\ b \end{matrix}$ with $\begin{matrix} \downarrow \\ \uparrow \end{matrix}$

Next we impose some relations:

$$\begin{array}{c} n-k \\ \nearrow \\ \text{---} \\ \searrow \\ k \end{array} = (-1)^{k(n-k)} \begin{array}{c} n-k \\ \searrow \\ \text{---} \\ \nearrow \\ k \end{array}$$

$$\begin{array}{c} k+l \\ \nearrow \\ \text{---} \\ \searrow \\ k+l \end{array} = \begin{bmatrix} k+l \\ l \end{bmatrix} \begin{array}{c} \nearrow \\ \text{---} \\ \searrow \\ k+l \end{array}$$

$$\begin{array}{c} k \\ \nearrow \\ \text{---} \\ \searrow \\ k \end{array} = \begin{bmatrix} n-k \\ l \end{bmatrix} \begin{array}{c} \nearrow \\ \text{---} \\ \searrow \\ k \end{array}$$

$$\begin{array}{c} \nearrow \\ \text{---} \\ \searrow \\ \nearrow \quad \searrow \\ k \quad l \quad m \end{array} = \begin{array}{c} \nearrow \\ \text{---} \\ \searrow \\ \nearrow \quad \searrow \\ k \quad l \quad m \end{array}$$

$$\begin{array}{c} \nearrow \\ \text{---} \\ \searrow \\ \nearrow \quad \searrow \\ r \quad s \end{array} = \begin{bmatrix} r+s \\ s \end{bmatrix} \begin{array}{c} \nearrow \\ \text{---} \\ \searrow \\ r+s \end{array}$$

and

$$\begin{array}{c} \nearrow \\ \text{---} \\ \searrow \\ \nearrow \quad \searrow \\ k \quad l \end{array} = \sum_t \begin{bmatrix} k-l+r-s \\ t \end{bmatrix} \begin{array}{c} \nearrow \\ \text{---} \\ \searrow \\ \nearrow \quad \searrow \\ k \quad l \end{array}$$

Theorem $\Gamma_n: Sp(SL_n) \rightarrow Rep(SL_n)$ is an equivalence of pivotal categories.

Proof We will build a commutative diagram

$$\begin{array}{ccccc}
 Lad_m^n & \longrightarrow & \dot{U}_q^*(gl_m) & & \\
 \downarrow & & \downarrow & \searrow \Phi_m & \\
 & & \dot{U}_q^n(gl_m) & & \\
 & & \downarrow \Psi_m & \swarrow \Phi_m^n & \\
 FSp(SL_n) & \longrightarrow & Sp(SL_n) & \xrightarrow{\Gamma_n} & Rep SL_n
 \end{array}$$

(Here Lad_m^n , $\dot{U}_q^n(gl_m)$, and many arrows, are still to be defined.)

① Γ_n is surjective on Hom spaces, because Φ_m^n is and the triangle commutes.

② Γ_n is injective:

Suppose $\Gamma_n(\omega) = 0$ and, without loss of generality, the source and target of ω are oriented upwards.

We can find some m , and a lift of ω to $\tilde{\omega} \in Lad_m^n$.

Now $\Phi_m^n(\tilde{\omega}) = 0$, by commutativity, but Φ_m^n is injective

so $\tilde{\omega} = 0$ and $\omega = 0$

□

We define the map Γ_n on generators, and check the relations hold via some q -combinatorics.

Why is there a map $U_q(\mathfrak{gl}_m) \rightarrow \text{Rep } SL_n$?

\Rightarrow skew Howe duality.

$\Lambda^\bullet(\mathbb{C}^n \otimes \mathbb{C}^m)$ carries commuting actions of SL_n and GL_m ;
indeed, these are each others commutants, so we have

$$\text{End}_{U_{\mathfrak{sl}_n}}(\Lambda^\bullet(\mathbb{C}^n \otimes \mathbb{C}^m)) \leftarrow U_{\mathfrak{gl}_m}.$$

$$\text{Now } \Lambda^\bullet(\mathbb{C}^n \otimes \mathbb{C}^m) = \Lambda^\bullet(\mathbb{C}^n \oplus \dots \oplus \mathbb{C}^n) = \bigoplus_{\underline{k}} \Lambda^{k_1} \mathbb{C}^n \otimes \dots \otimes \Lambda^{k_m} \mathbb{C}^n,$$

$$\text{so } \text{End}_{U_{\mathfrak{sl}_n}}(\Lambda^\bullet(\mathbb{C}^n \otimes \mathbb{C}^m)) = \bigoplus_{\underline{k}, \underline{\ell}} \text{Hom}(\Lambda^{\underline{k}} \mathbb{C}^n \rightarrow \Lambda^{\underline{\ell}} \mathbb{C}^n).$$

Let's use Lusztig's 'idempotent form' $\dot{U}_q(\mathfrak{gl}_m)$. Then

$$\text{Hom}(\Lambda^{\underline{k}} \mathbb{C}^n \rightarrow \Lambda^{\underline{\ell}} \mathbb{C}^n) \leftarrow \mathbb{1}_{\underline{\ell}} \dot{U}_q(\mathfrak{gl}_m) \mathbb{1}_{\underline{k}}$$

Where do generators go?

$$E_i \longmapsto \begin{array}{ccccccc} & & & k_i+1 & k_{i+1}-1 & & \\ & & & \uparrow & \nwarrow & \uparrow & \\ & & & & & & \\ & & & \uparrow & & \uparrow & \\ & & & k_i & k_{i+1} & & \end{array}$$

$$F_i \longmapsto \begin{array}{ccccccc} & & & & & & \\ & & & \uparrow & \nearrow & \uparrow & \\ & & & & & & \\ & & & \uparrow & & \uparrow & \\ & & & k_i & k_{i+1} & & \end{array}$$

What is the kernel of $U_{\mathfrak{gl}_m} \rightarrow \bigoplus_K \text{End}_{U_{\mathfrak{sl}_n}}(\Lambda^K(\mathbb{C}^n \otimes \mathbb{C}^m))$?

\Rightarrow it's generated by weight space idempotents

$$\{ \mathbb{1}_{\underline{k}} \mid \underline{k} \text{ is not a weight of } \Lambda^\bullet \mathbb{C}^n \otimes \mathbb{C}^m \}$$

Proof: Define I_λ to be the ideal in $U(\mathfrak{gl}_m)$ generated ~~by~~ by $\{ \mathbb{1}_{\nu} \mid \lambda \text{ does not dominate } \nu \}$

Lemma $U(\mathfrak{gl}_m)/I_\lambda = \bigoplus_{\mu \leq \lambda} \text{End}(V(\mu))$

Proof The LHS is finite dimensional, so by Artin-Wedderburn it suffices to ~~identify the~~ show that ~~the~~ its category of modules is semisimple with simples $V(\mu)$. for $\mu \leq \lambda$. \square

Now, skew Howe duality tells us that as $U_{\mathfrak{sl}_n} \otimes U_{\mathfrak{gl}_m}$ representations,

$$\Lambda^K(\mathbb{C}^n \otimes \mathbb{C}^m) = \bigoplus_{\mu} V(\mu^+) \otimes V(\mu)$$

where μ ranges over n -bounded ($0 \leq \mu_i \leq n$) weights of $U_{\mathfrak{gl}_m}$ and $\sum \mu = K$.

$$\begin{aligned} \text{Thus } \text{End}_{U_{\mathfrak{sl}_n}} \Lambda^K(\mathbb{C}^n \otimes \mathbb{C}^m) &= \bigoplus_{\mu} \text{End}(V(\mu)) \\ &= U(\mathfrak{gl}_m)/I_{\lambda(K)} \end{aligned}$$

where $\lambda(K) = (n, n, \dots, n, r, 0, \dots, 0)$, $\sum \lambda(K) = K$.

(The same argument works for $U_{\mathfrak{a}} \mathfrak{gl}_m$.) \square

That gives us

Next we need a map

$$\dot{U}_q^n(\mathfrak{gl}_m) \xrightarrow{\Psi_m^n} Sp(SL_n)$$

which we construct on generators:

$$E_i^{(r)} \mapsto \begin{array}{c} \uparrow \uparrow \uparrow \downarrow \uparrow \uparrow \uparrow \\ \uparrow \uparrow \uparrow \downarrow \uparrow \uparrow \uparrow \end{array}$$

$$F_i^{(r)} \mapsto \begin{array}{c} \uparrow \uparrow \uparrow \uparrow \uparrow \uparrow \uparrow \\ \uparrow \uparrow \uparrow \downarrow \uparrow \uparrow \uparrow \end{array}$$

We then need to verify that the relations of $\dot{U}_q(\mathfrak{gl}_m)$ hold.

$$\bullet E_i^{(r)} F_j^{(s)} = F_j^{(s)} E_i^{(r)} \quad (i \neq j)$$

Diagrammatic proof for the commutation relation $E_i^{(r)} F_j^{(s)} = F_j^{(s)} E_i^{(r)}$ for $i \neq j$. The diagram shows two vertical lines with r upward arrows on the left and s downward arrows on the right. The left side has the arrows on the left line, and the right side has the arrows on the right line. The two diagrams are shown to be equal.

$$\bullet E_i^{(r)} E_j^{(s)} = E_j^{(s)} E_i^{(r)} \quad (|i-j| > 1)$$

Diagrammatic proof for the commutation relation $E_i^{(r)} E_j^{(s)} = E_j^{(s)} E_i^{(r)}$ for $|i-j| > 1$. The diagram shows two vertical lines with r upward arrows on the left and s downward arrows on the right. The left side has the arrows on the left line, and the right side has the arrows on the right line. The two diagrams are shown to be equal.

$$\bullet E_i^{(s)} E_i^{(r)} = \begin{bmatrix} r+s \\ r \end{bmatrix} E_i^{(r+s)}$$

Diagrammatic proof for the relation $E_i^{(s)} E_i^{(r)} = \begin{bmatrix} r+s \\ r \end{bmatrix} E_i^{(r+s)}$. The diagram shows two vertical lines with r upward arrows on the left and s downward arrows on the right. The left side has the arrows on the left line, and the right side has the arrows on the right line. The two diagrams are shown to be equal.

proof: $\begin{array}{|c|} \hline \uparrow \\ \hline \downarrow \\ \hline \end{array} = \begin{array}{|c|} \hline \downarrow \\ \hline \uparrow \\ \hline \end{array} = \begin{bmatrix} r+s \\ r \end{bmatrix} \begin{array}{|c|} \hline \uparrow \\ \hline \uparrow \\ \hline \end{array}$

$$\bullet E_i^{(r)} F_i^{(s)} \mathbb{1}_k = \sum_t \begin{bmatrix} \langle k, d_i \rangle + r - s \\ t \end{bmatrix} F_i^{(s-t)} E_i^{(r-t)} \mathbb{1}_k$$

Diagrammatic proof for the relation $E_i^{(r)} F_i^{(s)} \mathbb{1}_k = \sum_t \begin{bmatrix} \langle k, d_i \rangle + r - s \\ t \end{bmatrix} F_i^{(s-t)} E_i^{(r-t)} \mathbb{1}_k$. The diagram shows a vertical line with r upward arrows on the left and s downward arrows on the right. The left side has the arrows on the left line, and the right side has the arrows on the right line. The two diagrams are shown to be equal.

(this is a relation in the spider already)

and finally the Serre relation

$$E_2 E_1 E_1 - [2] E_1 E_2 E_1 + E_1 E_1 E_2 = 0$$

proof

(applying the square switch relation)

□

Our final obligation is the rectangle

$$\begin{array}{ccc} \text{Lad}_m^n & \longrightarrow & \mathcal{U}_e^n(\mathcal{G}_m) \\ \downarrow & \nearrow & \downarrow \Psi_m^n \\ \text{FSp}(\text{SL}_n) & \longrightarrow & \text{Sp}(\text{SL}_n) \end{array}$$

and constructing the lift $\omega \mapsto \tilde{\omega} \in \text{Lad}_m^n$.

A ladder diagram is simply one of the form

and it is clear what all the maps in the rectangle are.

How do we convert an arbitrary spider diagram into a ladder diagram?

First, isotope all the vertices out to the right:

and then isotope D so everything is in generic position w.r.t. the x coordinate, and further every trivalent vertex looks like .

Now superimpose a vertical 0 or n strand to the right of each elementary piece, and make the local modification so a neighbourhood looks like a ladder.

Examples
